General

Guideline Title

Screening for thoracolumbar spinal injuries in blunt trauma: an Eastern Association for the Surgery of Trauma practice management guideline.

Bibliographic Source(s)

Guideline Status

This is the current release of the guideline.

The Eastern Association for the Surgery of Trauma (EAST) reaffirmed the currency of this guideline on October 16, 2017.

This guideline meets NGC's 2013 (revised) inclusion criteria.

Recommendations

Major Recommendations

The levels of recommendation (1-3) and classification of evidence (I-III) are defined at the end of the "Major Recommendations" field.

Level 1

When imaging is deemed necessary, multidetector computed tomographic (MDCT) scans with axial collimation should be used to screen for and diagnose, as MDCT scans are superior to plain films in identifying thoracolumbar spine (TLS) fractures.

Level 2
Patients with back pain, TLS tenderness on examination, neurologic deficits referable to the TLS, altered mental status, intoxication, distracting injuries, or known or suspected high-energy mechanisms should be screened for TLS injury with MDCT scan.

In blunt trauma patients with a known or suspected injury to the cervical spine, or any other region of the spine, thorough evaluation of the entire spine by MDCT scan should be strongly considered owing to a high incidence of spinal injury at multiple levels within this population. Patients without complaints of TLS pain that have normal mental status, as well as normal neurological and physical examinations may be excluded from TLS injury by clinical examination alone, without radiographic imaging, provided that there is no suspicion of high-energy mechanism or intoxication with alcohol or drugs.

Level 3

Magnetic resonance imaging (MRI) should be considered in consultation with the spine service for MDCT findings suggestive of neurologic involvement and of gross neurologic deficits.

Definitions:

Classes of Evidence

Class I: Prospective randomized clinical trial.

Class II: Prospective clinical studies or retrospective analyses based on reliable data such as cohort, observational, prevalence, or case-control studies.

Class III: Retrospectively collected data based on database or registry review, case series, or expert opinion.

Levels of Recommendations

Level 1: The recommendation is convincingly justifiable based on the available scientific information alone. This recommendation is usually based on Class I data; however, strong Class II evidence may form the basis for a Level 1 recommendation, especially if the issue does not lend itself to testing in a randomized format. Conversely, low-quality or contradictory Class I data may not be able to support a Level 1 recommendation.

Level 2: The recommendation is reasonably justifiable by available scientific evidence and strongly supported by expert opinion. This recommendation is usually supported by Class II data or a preponderance of Class III evidence.

Level 3: The recommendation is supported by available data but adequate scientific evidence is lacking. This recommendation is generally supported by Class III data. This type of recommendation is useful for educational purposes and in guiding future clinical research.

Intended Users
Advanced Practice Nurses
Nurses
Physician Assistants
Physicians

Guideline Objective(s)

- To provide evidence-based recommendations on the screening for thoracolumbar spinal (TLS) injuries in blunt trauma patients
- To revise and expand on the Eastern Association for the Surgery of Trauma (EAST) 2006 recommendations
- To answer the relevant questions regarding screening of the acute blunt trauma patient for TLS injuries:
  - What is the appropriate imaging modality to screen patients for TLS injuries?
  - Which trauma patients require radiographic screening for TLS injuries?
  - Does a patient who is awake and alert without distracting injuries require radiologic workup to rule out TLS injuries?

Target Population
Patients with thoracolumbar spinal injuries in blunt trauma

Interventions and Practices Considered

1. Multidetector computed tomographic scans (MDCT)
2. Clinical examination alone
3. Magnetic resonance imaging (MRI)
4. Spine service consultation

Major Outcomes Considered
Sensitivity and specificity of multidetector computed tomographic (MDCT) scans
Methodology

Methods Used to Collect/Select the Evidence

Hand-searches of Published Literature (Primary Sources)

Hand-searches of Published Literature (Secondary Sources)

Searches of Electronic Databases

Description of Methods Used to Collect/Select the Evidence

2012 Guideline

A search of the National Library of Medicine and the National Institutes of Health database and MEDLINE was performed using PubMed (www.pubmed.gov). The search identified articles in the English language that addressed the screening or identification of thoracolumbar spinal (TLS) injury from March 2005 to December 2011. Articles that were categorized as review articles, letters to the editor, editorials, commentaries, and case reports were excluded from the query.

2017 Reaffirmation

The guideline developer searched OvidSP and MEDLINE using the following search terms: Cervical Vertebrae/Diagnostic Imaging, Cervical Vertebrae/injuries, Humans, MRI, Spinal Injuries/diagnosis, Spinal Injuries/Diagnostic imaging, Thoracic Injuries/diagnosis, Thoracic Injuries/diagnostic Imaging, Tomography, X-Ray Computed, Wounds, Non penetrating /diagnosis, Wounds, non penetrating/diagnostic imaging, Practice Guideline as a Topic, Trauma Centers, Mass Screening, Practice Patterns, Physicians, and Practice Guidelines. The literature search was performed for Jan 2011-October 2017 and included all articles referenced using the above MeSH criteria during the time period were reviewed for subject matter and relevance and excluded non-trauma, non-English language, opinion papers, editorials, and non-human articles.

Number of Source Documents

2012 Guideline

Thirty-seven articles were distributed to the committee. Twelve of those articles were thought to be pertinent to the construction of the updated guidelines. An additional nine articles referenced in the previous Practice Management Guideline (PMG) were referenced to revise and validate the updated guidelines.

2017 Reaffirmation

Thirty-five articles were identified from the literature search and reviewed for reaffirmation of currency.

Methods Used to Assess the Quality and Strength of the Evidence

Weighting According to a Rating Scheme (Scheme Given)

Rating Scheme for the Strength of the Evidence

Class I: Prospective randomized clinical trial (no class I data exist)

Class II: Prospective clinical studies or retrospective analyses based on reliable data such as cohort,
observational, prevalence, or case-control studies (14 references)

Class III: Retrospectively collected data based on database or registry review, case series, or expert opinion (7 references)

Methods Used to Analyze the Evidence

Systematic Review with Evidence Tables

Description of the Methods Used to Analyze the Evidence

An evidentiary table was constructed using the 21 references that were identified. The evidentiary table is available online at http://links.lww.com/TA/A201. Articles were classified in accordance with the Eastern Association for the Surgery of Trauma (EAST) primer on evidence-based medicine that was published in 2000 (see the "Availability of Companion Documents" field). Articles were categorized as Class I, II, or III.

Methods Used to Formulate the Recommendations

Expert Consensus

Description of Methods Used to Formulate the Recommendations

2012 Guideline

Recommendations were then classified as Level 1, 2, or 3 according to definitions as defined by the Eastern Association for the Surgery of Trauma (EAST) primer on evidence-based medicine (see the "Rating Scheme for the Strength of the Recommendations" field).

2017 Reaffirmation

A comprehensive literature search was performed as referenced above. All articles were screened by title and abstract, and then all qualifying articles were reviewed by a single reviewer (SS). The final articles of relevance (N=4) were reviewed, of which 3 were additional support, including one large multi-institutional trial. The fourth article was a level IV retrospective study with specificity and sensitivity that were lower than acceptable to contradict the previous recommendations of this guideline without a focus on mechanism. Recent publications continue to support mechanism-based radiographic evaluation and the use of multi-detector computed tomographic (MDCT) scanning in comparison to physical exam or plain films for diagnosis of clinically significant thoracolumbar injury.

Rating Scheme for the Strength of the Recommendations

Level 1: The recommendation is convincingly justifiable based on the available scientific information alone. This recommendation is usually based on Class I data; however, strong Class II evidence may form the basis for a Level 1 recommendation, especially if the issue does not lend itself to testing in a randomized format. Conversely, low-quality or contradictory Class I data may not be able to support a Level 1 recommendation.

Level 2: The recommendation is reasonably justifiable by available scientific evidence and strongly supported by expert opinion. This recommendation is usually supported by Class II data or a preponderance of Class III evidence.

Level 3: The recommendation is supported by available data but adequate scientific evidence is lacking. This recommendation is generally supported by Class III data. This type of recommendation is useful for
Cost Analysis
The guideline developer reviewed published cost analyses.

Method of Guideline Validation
Not stated

Description of Method of Guideline Validation
Not applicable

Evidence Supporting the Recommendations

Type of Evidence Supporting the Recommendations
The type of supporting evidence is identified and graded for each recommendation (see the "Major Recommendations" field).

Benefits/Harms of Implementing the Guideline Recommendations

Potential Benefits
Appropriate screening of thoracolumbar spinal (TLS) injuries in blunt trauma patients

Potential Harms
Not stated

Qualifying Statements

Qualifying Statements
- The Practice Management Guidelines (PMGs) for the screening of thoracolumbar spine (TLS) injuries in blunt trauma were established to assist practitioners in the screening, diagnosis, and management of TLS injuries in blunt trauma patients. These are evidence-based guidelines that should be used in accordance with clinical judgment. Individual scenarios, resource availability, and clinical variations may need to be taken into consideration when determining ultimate screening algorithms.
- The Eastern Association for the Surgery of Trauma (EAST) is a multi-disciplinary professional society committed to improving the care of injured patients. The Ad hoc Committee for Practice Management Guideline Development of EAST develops and disseminates evidence-based information to increase the scientific knowledge needed to enhance patient and clinical decision-making, improve health care
quality, and promote efficiency in the organization of public and private systems of health care delivery. Unless specifically stated otherwise, the opinions expressed and statements made in this publication reflect the authors' personal observations and do not imply endorsement by nor official policy of EAST.

- “Clinical practice guidelines are systematically developed statements to assist practitioner and patient decisions about appropriate health care for specific clinical circumstances.”* These guidelines are not fixed protocols that must be followed, but are intended for health care professionals and providers to consider. While they identify and describe generally recommended courses of intervention, they are not presented as a substitute for the advice of a physician or other knowledgeable health care professional or provider. Individual patients may require different treatments from those specified in a given guideline. Guidelines are not entirely inclusive or exclusive of all methods of reasonable care that can obtain/produce the same results. While guidelines can be written that take into account variations in clinical settings, resources, or common patient characteristics, they cannot address the unique needs of each patient nor the combination of resources available to a particular community or health care professional or provider. Deviations from clinical practice guidelines may be justified by individual circumstances. Thus, guidelines must be applied based on individual patient needs using professional judgment.

Implementation of the Guideline

Description of Implementation Strategy

An implementation strategy was not provided.
